# 1 Introduction

## 1.1 Generic Application

A typical application can be broken down into three logical layers namely:-

- **Presentation Layer:** It is the layer responsible for display information and collect information from the user.
- **Business Logic Layer:** In this layer, information collected from presentation layer is used to perform the various calculations and operations needed to be performed by the application.
- **Data Layer:** This layer is responsible for storing and retrieving data to be used by other layers.

Data Layer is typically implemented using a database, which is an organized collection of data. A database can be of two types : Centralized and Distributed.

## 1.2 Disadvantages of a centralized database

Most applications require data in some form or another and need to store the said data for future use, this is where databases come into picture. A database is an organized collection of data, generally stored and accessed electronically from a computer system. Access to this data is usually provided by a "database management system" (DBMS) consisting of an integrated set of computer software that allows users to interact with one databases and provides access to all of the data contained in the database. DBMS's provide various functions that allow management of a database and its data such as Data definition which defines the database model i.e. the logical structure of the data model, Updating of actual data which includes insertion, modification, and deletion of the actual data, Retrieval of actual data which may or may not include data processing and Administration which includes allowing access to various users, enforcing data security and various other checks. [1] A database model is a type of data model that determines the logical structure of a database and fundamentally determines in which manner data can be stored, organized and manipulated. The most popular example of a database model is the relational model, which uses a table-based format. The ACID (Atomicity, Consistency, Isolation and Durability) database design is one of oldest and most important database design. A relational database that fails to follow the ACID model cannot be considered reliable.

Databases can be categorized in many categories depending on how they store data, where it is stored and the additional functionality the DBMS can provide on the stored data. Broadly databases can be categorized into two major categories centralized and distributed. They both have their advantages and disadvantages. A centralized database is a database that is located, stored, and

maintained in a single location and has a single DBMS but can be accessed by the users distributed in the network. A distributed database system consists of a collection of local databases, geographically located in different points (nodes of a network of computers) and logically related by functional relations so that they can be viewed globally as a single database [2]. There are two types of distributed databases homogeneous and heterogeneous. In a homogeneous distributed database all the locations store the database identically i.e. all locations have the same management system and schema. Whereas in heterogeneous distributed database different locations can have different management software, schemas. For a database management system to be distributed, it should be fully compliant with the twelve rules introduced by C.J. Date in 1987 [3]: local autonomy; the absence of a dependency from a central location; continuous operation; location independent; fragmentation independent; replication independent; distributed query processing; distributed transaction management; hardware independent; operating system independent; independent of communication infrastructure; independent of database management system.

If a centralized database is used to store the data then the whole system is prone to Single Point of Failure, if for some reason the database fails the whole system will fail. As all the data is stored in a single location, if there are no precautionary measures taken then a hardware failure can lead to complete data loss. The databases are also vulnerable to cyberattacks which can cause data loss, data leaks, data inconsistency and many other vulnerability. This makes centralized database dubious with very low reliability. But at the same time, centralized database ensures data consistency and easy management in compliance with ACID design [4].

A major advantage of distributed database is that by sharing a database across multiple nodes can obtain a storage space extension and also can benefit from multiple processing resources. A distributed database system is robust to failure to some extent. Hence, it is reliable when compared to a centralized database system. It is also more robust compared to a centralized database as it doesn't have a single point of failure, if a node fails another node or group of nodes can provide the necessary data. But to make this possible complex software's are required which incur additional costs and processing overheads. Maintaining data integrity is difficult and hence minimum redundancy and ACID properties are more relaxed than compared to a centralized database [4]. Distributed environment also faces problems such as fragmentation and data replication. A data fragment constitutes some subset of the original database. A data replica constitutes some copy of the whole or part of the original database. The fragmentation and the replication can be combined: a relationship can be partitioned into several pieces and can have multiple replicas of each fragment [5].

### 1.3 Advantages of using Blockchain

Blockchain is a type of decentralized database where the data is stored in blocks and each block is linked to the previous block using its cryptographic hash, thus forming a chain. As the blockchain grows in size, it becomes more and more difficult to tamper the data in these blocks. Blockchain based databases are more trustworthy, reliable and secure than traditional databases.

A blockchain based system is decentralized. Hence, a centralized authority is not necessary. Decentralized systems are also resilient to single point of failure. A blockchain network comprises of various nodes, each maintaining its own copy of database. Hence, all the data is replicated, shared and synchronized across all the nodes in the network. This makes the data almost tamper proof as it will be very costly and thus highly unlikely for a malicious person to change the data across the whole network. No node can directly write data to the blockchain as it can make the data inconsistent, to avoid this the blockchain network uses a consensus algorithm which helps all the nodes in the network to come to a consensus and commit the data in the blockchain. This helps to keep all the nodes in the network to get synchronized with each other.

The data that is committed to the blockchain is immutable. After some data is inserted into the blockchain, it is very difficult to delete or alter it. This is realized by including, in each block, the cryptographic hash of its previous block. Because of this immutability, a blockchain database only supports read and write operations in contrast to traditional databases which supports read, write, update and delete operations. To update the database state, a subsequent write is required. Old writes persist in the blockchain forever, making it convenient to trace how the blockchain database state is updated over time. This makes it possible to trace the actions that resulted in a particular database state.

Another benefit of blockchain is that it provides transparency to the data stored in it. This is achieved by replicating the blockchain data among multiple nodes present in the blockchain network. Nodes in the blockchain network not only can view the data already committed to the blockchain but can also participate in the process of validating the data to be committed in the blockchain. The transparency also helps users to cross verify some data against the blockchain.

A blockchain ledger is logically a single public ledger. Since every node updates its copy of blockchain ledger in sync with each other and after consensus is reached, the whole network logically act as one single public ledger. This removes the complications present in traditional systems where different participants or organizations maintains multiple ledgers which needs to be reconcile and synchronized time to time.

Systems that are deployed on public blockchain network are more cost efficient as compared to the traditional systems. This is because the system utilizes the processing power and resources of a large number of nodes that are already connected to the blockchain network, thus significantly reducing the cost needed for setting up and maintaining centralized servers present in traditional systems.

Blockchain based systems are more secure and resilient to cyber attacks, which can cause data loss, data leaks, data inconsistency and many other vulnerability, than traditional systems. Whenever a new block is introduced in the blockchain, its hash value is calculated which also includes the hash of its previous block. If a malicious user fraudulently tries to tamper the data inside a block, not only its hash value changes, but the hashes of the following blocks get changed too. This, along with the fact, that the data is stored in multiple nodes present in the blockchain network, makes it very difficult to tamper the data present in the blockchain.

## 1.4 Motivation

In India, currently if person is asked to prove if he/she is the owner of a piece of land then all they can show for it is a sale deed which just proves that the person was the owner at a particular time, but that person cannot prove that he/she is still the owner of that land. For proving the same he/she has to go to various government offices and collect various document showing that no sale deed has been registered for that land after the one which the person has. When a person wishes to buy land in India, they have to be very careful and perform various checks such as

- Check if the deed title is in the name of the seller and if he/she has the full right to sell it
- Procure a Encumbrance Certificate from sub-registrar's office where the deed is registered which declares that the land is free of any legal hassle and unpaid dues
- Check if the Property tax and other bills are paid in full and the seller has the respective original receipts
- Check if the loan on the land has been completely repaid

If a buyer is lethargic in verifying these documents he/she can be easily duped into buying a disputed land parcel or it may even happen that the land in question did not even legally belong to the said seller, that is the seller was not the genuine owner of that land provided fake documents. As these documents are mostly maintained offline as hard copies these cases occur often.

Getting all the information such as the sale deeds and ownership history for a land parcel is very cumbersome, a simple solution to this problem is a smartphone application with which users/potential buyers can get land ownership history and related documents for a particular land parcel. These documents and data can be stored in a database by the government and will be updated every time a new sale deed is registered i.e. owner for a land parcel changes. This makes the process of acquiring the documents in question very easy and hassle free.

Indian government launched Digital India Land Record Modernization Programme in 2008. Main aim of this programme is to create a system of updated land records, automated and automatic mutation, integration between textual and spatial records, inter-connectivity between revenue and registration, to replace the present deeds registration and presumptive title system with that of conclusive titling with title guarantee [6]. In addition to this, Indian government also plans on storing the digital records on a private blockchain and provide a system where citizens can view the ownership details and complete history of the property before going in for the purchase [7].

## 1.5 Proposed Solution

To tackle the problem of accessing and verifying the land ownership records, this paper proposes a smartphone based solution. Using which users can request land ownership records for a particular land parcel by taking the advantage of the GPS module available in smartphones. These land ownership records are stored in a permissioned blockchain and to make it backwards compatible i.e. migrating old records to the new system, scanned copies of the documents can be stored in permissioned IPFS cluster with their Content Identifier (CID) stored on the same blockchain. Now whenever users want the ownership history of a land parcel they use the smartphone application, mark the piece of land and after successful completion of the process they get a PDF report with the ownership history of that said land parcel. This PDF report also contains verification codes for each ownership record they hold, these verification codes can then be used on a verification portal to generate a digitally signed PDF verifying that the given information is true. This solution hence provides a trustful and hassle free mechanism for people to access and verify land ownership records.

## 2 Chapter 3

### 2.1 Records Server

This serves a web application that allows users in Land Registration Department to enter and query land records on blockchain. To support migration of old land records onto the new platform, uploading scanned documents with each transaction such as adding a land record, transferring a land or splitting a land record is supported. All the documents are stored in the IPFS.

For each land record, a PDF certificate, digitally signed by the Land Registration Department, is generated which includes all the information about the land such as the current owner, khasra number etc. This certificate is stored in the IPFS.

For each land transfer, a PDF certificate, digitally signed by the Land Registration Department, is generated which includes all the information related to the land transfer. This certificate is stored in the IPFS. In a land transfer, land record certificate is also updated to reflect the current owner.

This web application provides following operations to the user :-

- Add Land Record :- Add a land record.
- Transfer Land :- Transfer land ownership.
- Split Land :- Splits a land record into two separate land records, useful in cases when a part of land needs to be transferred.
- Query Records :- Users can query records in any particular State, Sub-District, District or Village.
- Query Ownership History :- Users can query ownership history of a particular land.

Records server is implemented using Express framework, a NodeJS module.

#### 2.1.1 Add Land Record

Adding a land record is added to the blockchain entails:-

1. Get input from user.
2. Generate certificate from the details.
3. Upload certificate to IPFS and receive CID for the certificate.
4. Create land record on the blockchain

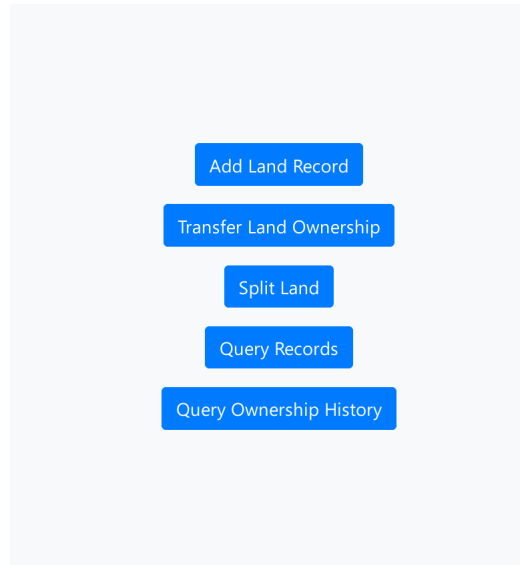

Figure 1: Home Page

### Add Land

### 2.1.2 Transfer Land

Transferring a land record entails :-

1. Get input from user.
2. Generate land transfer certificate containing details about the land transfer.
3. Generate land record certificate containing details about the land and current owner.
4. Upload certificates to IPFS and receive CIDs for the certificates.
5. Create land transfer record and update land record on the blockchain.

### 2.1.3 Split Land Record

Splitting a land record entails :-

1. Get input from user.
2. Generate certificates for the two land records.
3. Add two new land records and mark old land record as expired on blockchain.

### 2.1.4 Query Records

Users can query all the records in a particular village or sub-district. Querying records entails :-

1. Get input from user.
2. Query records from blockchain.

## Transfer Land

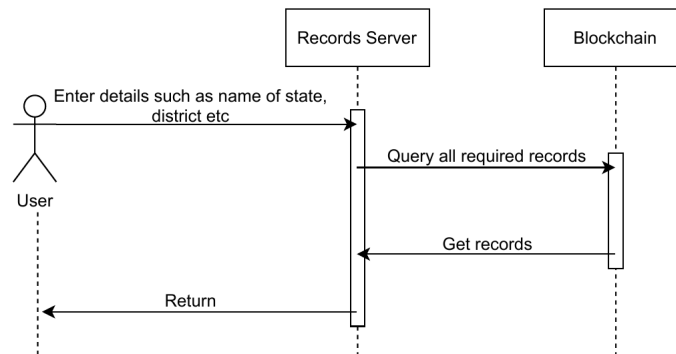

Figure 9: Sequence diagram for querying records

### 2.1.5 Query Records

Users can query ownership history of a particular land. Querying records entails :-

1. Get input from user.
2. Query records from blockchain.

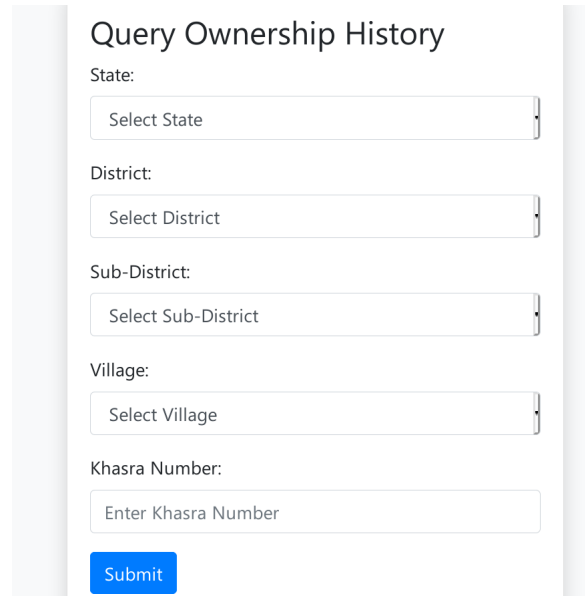

A web form titled "Query Ownership History" with a light gray background. It contains five input fields: "State:" with a dropdown menu showing "Select State"; "District:" with a dropdown menu showing "Select District"; "Sub-District:" with a dropdown menu showing "Select Sub-District"; "Village:" with a dropdown menu showing "Select Village"; and "Khasra Number:" with a text input field showing "Enter Khasra Number". Below these fields is a blue "Submit" button.

Figure 10: Query Land Ownership History

## 2.2 Smartphone Application

This application is used to interact with LRSP Server and provide a user friendly mechanism for the users to request land ownership history records. Through the application users can Login or Register themselves after which they can ask for land records by marking the land parcel on map presented on the screen. The marked GPS coordinates are then sent to the LRSP server which checks if they exists in the blockchain. If no, then an error is displayed to the users and if yes, then a second screen with the land parcel highlighted on the map with other necessary information of the land parcel is displayed. The user can now verify that they querying for the correct land parcel and if they wish to continue, they are redirected to a payment gateway i.e. Razorpay gateway. If the transaction is completed successfully then the Payment ID and Payment Signature are sent to the LRSP Server for verification and on positive verification the server proceeds to generate and send the PDF to the user email

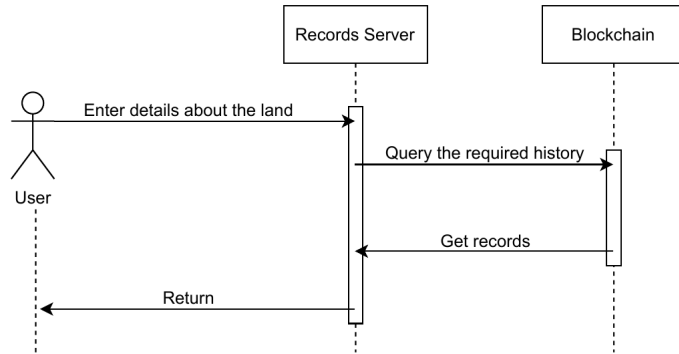

Figure 11: Sequence diagram for querying land ownership history

address and a success screen is displayed on the application. If the transaction fails then an error screen is displayed prompting the user to redo the process.

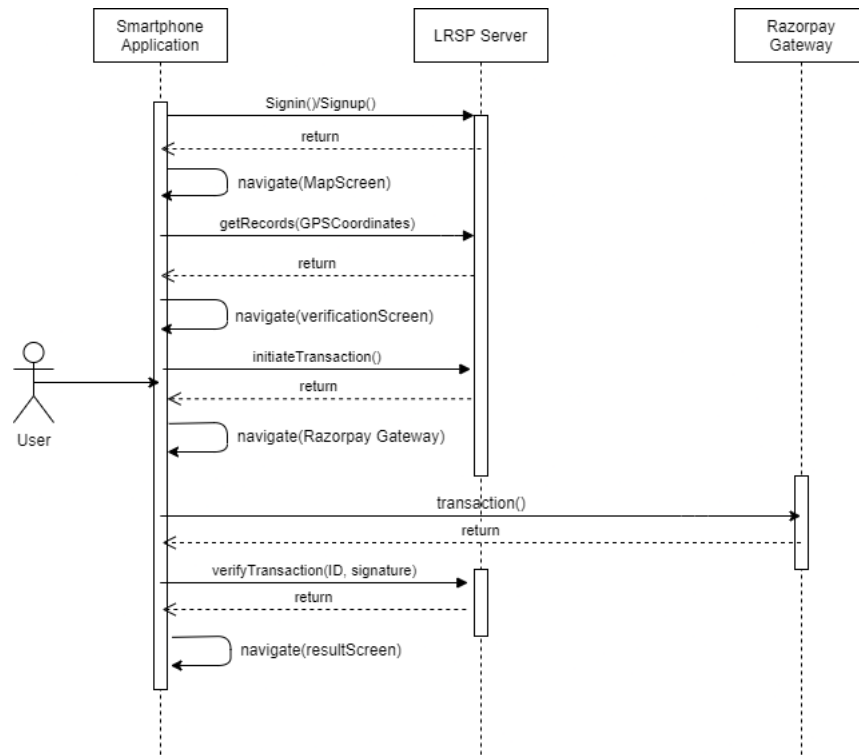

Figure 12: Sequence diagram for smartphone application

The application is built using React Native which is JavaScript library that is used to build cross-platform applications using a single React code base i.e. we can build both Android and iOS application using the same code base.

## **2.3 LRSP Server**

It is a Node server that interacts with the smartphone application to provide the requested land record to the user. It acts as an intermediary between the LRSP smartphone application and the Blockchain network. The application sends GPS coordinates to the LRSP server requesting for the land record. The server resolves it and fetches the corresponding land record information from the Blockchain. The land record is mailed to the user once the user completes the payment. It supports HTTPS for secured interaction.

The server also provides user authentication functionality to the LRSP system. It uses a centralized database to register users with the system. It uses JWT-based stateless authentication to allow access to protected routes.

LRSP server is implemented using Express framework, a NodeJS module.

### **2.3.1 Sequence Flow**

The server resolves the GPS coordinates obtained from the application to get the corresponding State, District, Sub-District and village information. This is accomplished by using an external Reverse Geocoding service. The server interacts with the Blockchain network to fetch the corresponding record. The records are queried at village, sub-district and district levels in order. Once the record is found, the PDF is generated and mailed to the user after payment is verified. The generated PDF contains the hash IDs of the certificates stored on IPFS. To validate the land record, the user can request for these certificates from the verification server.

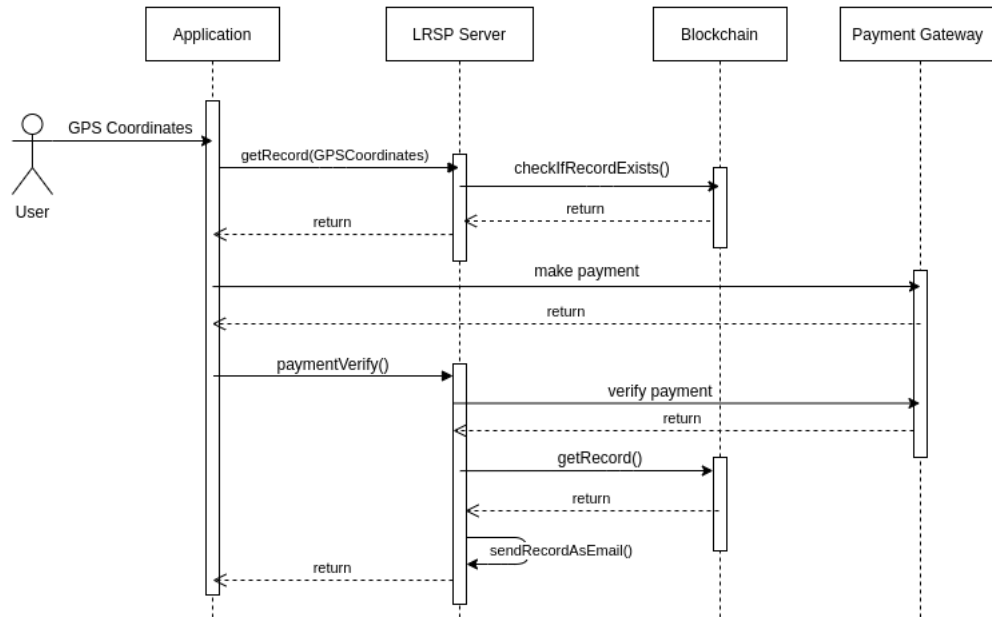

Figure 13: LRSP server sequence diagram

### 2.3.2 Usage

Following are the web endpoints exposed by the LRSP server:

- **POST** /signup:

This endpoint is used to register a new user to the LRSP server. If successful, it returns the jwt access token in the response body. The jwt token expires in 1 hour.

**Request Parameters:**

- name: user name
- email: user email address
- password: user password

**Success Response:**

```

{
  "success": "true"
  "token": <jwt_token>
}
  
```

- **POST** /login:

This endpoint is used to get the jwt access token to access protected endpoints. The jwt token expires in 1 hour.

**Request Parameters:**

- email: user email address
- password: user password

**Success Response:**

```
{  
  "success": true  
  "token": <jwt_token>  
}
```

- **GET** /landrecord

This endpoint is used to get the land information corresponding to a particular GPS coordinates that includes khasra no, subdistrict, district, state and vertex points of land boundary.

**Require Authentication:** True

**Request Parameters:**

- lat: GPS coordinate latitude
- lon: GPS coordinate longitude

**Success Response:**

```

{
  "success": true,
  "data": {
    "khasra": "1",
    "village": "abu said",
    "subDistrict": "ajnala",
    "district": "amritsar",
    "state": "punjab",
    "points": [
      {
        "lat": "31.894083",
        "lon": "74.834157"
      },
      {
        "lat": "31.894229",
        "lon": "74.835573"
      },
      {
        "lat": "31.892662",
        "lon": "74.835723"
      },
      {
        "lat": "31.892708",
        "lon": "74.833642"
      }
    ]
  }
}

```

- **GET** /payment/initiate

This endpoint is used to initiate a payment request to obtain the requested land record.

**Require Authentication:** True

**Request Parameters:**

- khasraNo: khasra no of land
- village: Village name corresponding to land.
- subDistrict: Sub-District name corresponding to land
- district: District name corresponding to land
- state: State name corresponding to land

#### Success Response:

```
{
  "order_id": 1234
  "amount": 100
}
```

- **GET** /payment/verify

This endpoint is used to initiate a payment request to obtain the requested land record.

**Require Authentication:** True

**Request Parameters:**

- order\_id:
- razorpay\_order\_id:
- razorpay\_payment\_id:
- razorpay\_signature:

**Success Response:**

```
{
  "success": true,
}
```

## 2.4 Verification Server

The verification server provides a portal to obtain the PDF certificates issued by Land Registration Department. The certificates are digitally signed by the respective authorities and contains information regarding land records and transactions. These certificates provide a proof for land ownership and transactions and can be used for validation purposes.

Verification server is implemented as a Node server using ExpressJS.

### 2.4.1 Types of Certificates

Land Registration Department issues two types of certificates:

- *Land Ownership Certificate* :- This certificate is issued corresponding to each land parcel and provides the ownership detail of a land.
- *Land Transaction Certificate* :- This certificate is issued for each land transaction and provides the land transaction details such as information about previous and new owner, sale price, etc.

#### 2.4.2 Sequence Flow

The sequence flow of verification server comprises of the following steps:

1. Get input from the user which includes IPFS hash of the certificate and record details.
2. Fetch the corresponding record from the Blockchain network.
3. Validate the provided certificate IPFS hash against the one associated with the record in the Blockchain.
4. If certificate hashes matched, fetch the stored certificate from IPFS.
5. Add digital signature to certificate with timestamp and send it to user.
